(57) Abstract

A machine (10) for dispensing a plurality of ingredients includes stepped arrays of canisters (56, 58) providing a source of materials. The bottom ends of the canisters are generally coplanar, and are positioned immediately above a low profile drive train (50) mounted on a tray (52). The drive train includes two spaced arrays of pumps (66) with a motor (68) providing a common drive for the pumps, mounted between the arrays. A valve tray (90) is located above the canisters and includes a low profile dispense head (44), an array of tubing members (240) arranged side-by-side in a common, generally horizontal plane, and an array of dispense valves (60) attached at the back of the valve tray. The dispense valves are coupled to the pumps by pairs of fluid lines (260, 262), so as to circulate materials between the pumps and dispense valves.

Modular Dispenser for Multiple Fluids

BACKGROUND OF THE INVENTION

1. Field of the Invention:

The present invention pertains to dispensing
5 apparatus, and in particular to apparatus for
dispensing fluids and other flowable materials.

2. Description of the Related Art:

Over the years, the assignee of the present
invention has developed dispensers for liquid colorants
10 and other commercially important materials. Examples
of automatic dispensers are given in United States
Letters Patent 3,851,798 and United States Design
Letters Patents 262,628 and 262,629. Dispensers of
this type typically have the capability to receive
15 instructions designating a selected formulation, and to
dispense the ingredients called for in the formulation.
Dispensing is carried out by pump assemblies which are
located at the bottom of the dispensing machine, behind
an array of canisters. A fluid coupling line extends
20 from the pump assemblies to passageways formed in a
nozzle member, where the ingredients leave the
dispenser apparatus. In other types of dispensing
machines, developed later, dispensing valves are
located remote from the pumping units, in the general
25 vicinity of a dispense head, and, for this reason, and
for a number of other factors, different dispensing
characteristics are observed among the different
systems.

Retail stores undergo continuing pressures to
30 increase the density of products displayed and made
available to consumers for carrying to a checkout area.
Paint departments of retail stores, for example, are
seeking more compact dispensing machines, and in

particular compact machines having a reduced "footprint," requiring less floor space than previous models. Because of assembly costs and the impact of component location on dispensing performance, 5 considerable care must be taken when reducing the overall size of a dispensing machine.

As will be readily appreciated by those skilled in the art, dispensing machines employ a substantial number of components which must be 10 maintained, and sometimes adjusted, throughout the life of the machine. It is important that field service personnel have ready access to all of the machine's parts and especially critical components, such as dispense valves and components associated with the 15 dispense valves for metering material required by a user of the machine. The pumps employed in dispensing machines are typically driven by one or more electric motors through some sort of intermediate mechanical transmission system. Moving parts are subject to wear 20 during the life of the machine, and provision must be made for their servicing.

During the construction of a complicated machine, such as dispensers of the above-mentioned type, various components are mounted within a framework 25 to which an outer "skin" (oftentimes comprising sheet metal panels) is applied. Alternatively, the outer skin may be applied to the framework to form a cabinet within which the components are installed. As a machine is constructed, various components are 30 accumulated and installed in a sequence which minimizes labor investment in the machine. Because of the nature of a commercial dispensing machine, many of the components of the machine comprise duplicates of the same part. For example, dispensing machines, 35 especially those used in the coatings industry, dispense multiple materials, as many as sixteen

different colorant materials, and oftentimes as many as
nine or twelve different colorant materials. Each
colorant material has its own "fluid circuit" typically
originating with a canister in which fluid material is
5 stored and terminating with the dispense head in which
fluid material leaves the dispenser. Fluid circuits
typically include, in addition to the aforementioned
canisters, pumps, valves and intermediate fluid lines.
Certain advantages can be attained if similar
10 components are associated together in subassemblies
which can be tested at one time.

SUMMARY OF THE INVENTION

It is an object of the present invention to
provide a dispensing machine in which components of
15 like type are aggregated in functional subassemblies,
which can be remotely tested prior to their
installation in a dispensing machine.

Another object of the present invention is to
reduce the space required for components in a
20 subassembly, employing the advantages of a "bench
assembly" wherever possible.

A further object according to principles of
the present invention is to provide dispensing
apparatus having a reduced "footprint," thereby
25 requiring a lesser amount of floor space, without
sacrificing functionality of the machine.

A further object according to principles of
the present invention is to provide dispensing
apparatus having improved construction which
30 facilitates field servicing and adjustments.

Yet another object according to principles of
the present invention is to provide a dispensing
machine which can readily accommodate store personnel
who must manually position containers of substantial
35 size and weight under a dispense head. For example, in

the coatings industry, tinting materials are added to base coatings provided by the manufacture in 5-gallon container sizes. It is an object of the present invention to provide a dispensing machine having a
5 shelf arrangement which required minimum lifting of these and other containers which receive dispense materials.

These and other objects to principles of present invention are provided in a dispensing
10 apparatus, comprising:

a frame;

a drive assembly including a base plate and a plurality of pumps mounted on the base plate;

a first plurality of canisters having top and
15 bottom ends and preselected shorter length, coupled to first ones of the pumps;

a second plurality of canisters, of preselected longer length and having top and bottom ends and coupled to second ones of the pumps;

20 the bottom ends of the first and the second plurality of canisters arranged generally coplanar, immediately above the drive assembly;

a lower shelf mounted to the frame above the first plurality of canisters and hinged to allow access
25 to the first plurality of canisters;

a dispense head coupled to the pumps and located above the canisters so as to overhang the lower shelf;

an access door above the second plurality of
30 canisters and hinged to allow access to the second plurality of canisters;

an upper shelf extending from the access door so as to be interposed between the lower shelf and the dispense head.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a perspective view of dispensing apparatus according to principles of the present invention;

5 FIG. 2 is a front elevational view thereof;
 FIG. 3 is a side elevational view thereof;
 FIG. 4 is a side elevational view of selected components disposed within the outer cabinet;

 FIG. 5 is a rear elevational view of the
10 dispenser apparatus;

 FIG. 6 is an exploded side elevational view of subassemblies of the dispensing apparatus;

 FIG. 7 is a top plan view of pump subassembly thereof;

15 FIG. 8 is a side elevational view thereof;
 FIG. 9 is a side elevational view similar to that of FIG. 8, but prior to installation of the pumps;

 FIG. 10 is a front elevational view of the pump subassembly;

20 FIG. 11 is a top plan view of one of the pumps;

 FIG. 12 is a side elevational view thereof;

 FIG. 13 is a rear elevational view thereof;

25 FIG. 14 is a cross-sectional view taken along the line 14-14 of FIG. 11;

 FIG. 15 is a perspective view of the valve tray assembly thereof;

 FIG. 16 is a top plan view thereof;

 FIG. 17 is a front elevational view thereof;

30 FIG. 18 is a side elevational view thereof;

 FIG. 19 is a rear elevational view thereof;

 FIG. 20 is a top plan view of a dispense head assembly thereof;

 FIG. 21 is a front elevational view thereof;

35 and

 FIG. 22 is a bottom plan view thereof.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT.

Referring now to the drawings, and initially to FIGS. 1-3, a dispenser illustrating principles of the present invention is generally indicated at 10.

5 The dispenser 10 has found immediate commercial acceptance in the field of retail and industrial coatings, particularly coatings which are blended on demand, using liquid components. As will be appreciated upon consideration of the following, the
10 dispenser 10 and associated apparatus therein may also be readily adaptable for use with other flowable materials including relatively thick pastes (such as ink pastes), salves, balms, food products and food supplements, as well as lotions and creams for topical
15 applications, for example.

The dispenser 10 includes a cabinet comprising an outer skin, preferably made of sheet metal components, affixed to a framework, preferably of tubular metal construction. The cabinet 12 includes a
20 lower portion 14 including side panels 16 and front panel 18, with access doors 20 formed in the side panel 16. As will be seen herein, the lower cabinet portion 14 encloses most of the storage canisters containing ingredients to be dispensed, pumps and pump drive
25 systems which deliver the materials to a dispense head located in the lower part of upper cabinet portion 24.

Dispenser 10 has a significantly reduced size. In particular, the "footprint" or base of the cabinet 12 is substantially smaller than previous
30 dispensers providing generally the same functionality. As will be seen herein, the space savings results from innovative assembly techniques which also provide substantial labor reduction for both installation and servicing of the dispenser.

35 Space reduction also results, in part, from the use of different sized canisters, and in

particular, canisters of different lengths. A middle section 26 of cabinet 12 houses the upper parts of the taller canisters and also houses tubing coupling the dispense nozzle to pumps located in the lower cabinet portion 14. The middle cabinet portion 26 includes a hinged access door 30 which can be opened, as desired, to service the taller canisters. A lower shelf 32 also serves as a second access door for servicing the shorter canisters located therebelow. Shelf 32 provides a convenient support surface for larger sized containers, allowing the containers to be conveniently positioned underneath the dispense nozzle, located in the overhanging lower portion of the upper cabinet part 24. It has been found expedient, particularly when dispensing paint materials into smaller sized containers, that the small size containers be positioned as close to the dispense nozzle as possible. Accordingly, an upper shelf 34 extends from access door 30 to support the smaller sized containers above the lower shelf 32. When dispensing into larger containers, the upper shelf 34 is hinged to swing out of the way, against front surface 36.

The upper dispenser portion 24 encloses most of the control equipment generally indicated at 72 for the dispenser, including a digital controller, a keyboard for data input, a visual display and printer for data output, and memory units for program and formulation storage. As can be seen in FIGS. 2 and 3, the upper cabinet portion 24 also includes a dispense head assembly 44.

Referring to FIGS. 4 and 5, a pump assembly generally indicated at 50 is mounted on a base plate 52, which includes casters 54 for convenient movement of dispenser 10. As mentioned, the pump assembly 50 is located in the lower cabinet portion 14 and, as can be seen in FIG. 4, is located at the bottommost portion of

the dispenser. In the preferred embodiment, two pluralities of canisters, each having a respective uniform size, are employed. An array of shorter canisters 56 is located underneath lower shelf 32 while
5 an array of taller canisters 58 is located underneath access door 30. As indicated in FIG. 4, the canisters and pump assembly are connected through tubing to a plurality of dispense valves 60, preferably located in the bottom part of upper cabinet portion 24. As will
10 be seen herein, the dispense valves 60 and dispense head assembly 44 are mounted together in a modular valve assembly.

Referring again to FIG. 4, pump assembly 50 includes a plurality of pumps 66 coupled to an electric
15 motor 68. The pumps 66 are preferably located in a common horizontal plane lying close to the horizontal centerline of motor 68, so as to provide a "flat" or "low profile" package. As can be seen in FIG. 4, the bottom ends of shorter canisters 56 and longer
20 canisters 58 are generally coterminous, so as to lie generally in a common horizontal plane positioned immediately above the horizontal, low profile assembly 50. As can be seen in FIG. 4, the preferred embodiment of dispenser 10 includes three rows of canisters, two
25 rows of shorter canisters and a row of longer canisters. In the preferred embodiment, each row is three canisters deep, with the dispenser having a total of nine canisters. If desired, each row of canisters could be made four canisters deep to provide a total of
30 twelve canisters, with only a small size increase being required for the additional canisters.

Referring now to FIG. 6, electronic control components generally indicated at 72 are installed in the upper part 24 of the dispenser cabinet. The
35 electronic components include a microprocessor controller and associated circuitry for receiving

commands from a keyboard 74 mounted in the front part of cabinet portion 24. The control circuitry is coupled to shaft encoders 102 on pumps 66 (see FIG. 7) to monitor the amounts of materials being dispensed
5 during a controlled operation. In the preferred embodiment, the pumps are operated apart from the controlled dispense cycles so as to circulate materials between the pumps, the dispense valve 60 and the canisters 56, 58. The control circuitry is also
10 coupled to dispense valve 60 to initiate and terminate a dispense operation, preferably by diverting circulating flow through the dispense valves to dispense head assembly 44. The control circuitry includes the necessary memory to store a variety of
15 control operations. In the preferred embodiment, the formulations for a particular family of materials being dispensed is stored in a separate formula storage device 78, which also includes a visual display 80 for outputting data to an operator. Data is also outputted
20 in hard copy form via a printer 82 mounted on the front of upper cabinet portion 24, alongside the formula storage device 78, and is also indicated by visual display 83.

In the preferred embodiment, the dispense
25 valves 60 and dispense head assembly 44 are mounted on a common valve tray subassembly generally indicated at 90. As will be seen herein, the valve tray subassembly 90 can be fabricated externally, on a bench or assembly line environment. The electronics components 72 are
30 likewise remotely fabricated, and brought to the machine assembly site, along with formula storage device 78, keyboard 74 and printer 82. The canisters are preferably arranged in two arrays, a first array for the six shorter canisters 56 and a second array for
35 the three longer canisters 58.

Significant construction advantages have been attained by fabricating the pump assembly 50 separately, as a separate subassembly unit. The cabinet with the aforementioned components is preferably erected separately and is brought to the dispenser assembly site as a complete unit, where it is merged with the pump assembly 50 to form the dispenser 10 (see FIG. 6).

Substantial advantages can be attained with the modular constructions identified above. For example, a basic dispensing machine can be designed ahead of time, awaiting a particular customer order. Depending upon the materials to be dispensed by the customer, various components of the basic design may have to be substituted. For example, large volume dispensing operations may best be served by a dispense system having greater throughput rates. For example, if a larger capacity dispense head is required, a special valve tray assembly can be fabricated on a bench, and tested as a working unit prior to installation in the dispenser cabinet. Similarly, larger capacity pumps may be required and/or a larger capacity motor or a motor operating at a faster speed may be desired for a particular installation. It is a much simpler matter to substitute the desired components of the pump assembly on a test bench. If desired, several different versions of subassemblies can be stocked to meet most customer's requirements, and the lead time required for supplying custom built machines can be drastically reduced with the modular construction of the present invention. Additionally, the designers of the machine can arrange the elements of the pump assembly more densely than would otherwise be practically feasible.

Referring now to FIGS. 7-10, the pump assembly 50 will be described in greater detail. As

mentioned above, motor 68 and pumps 66 are coupled together (i.e., either directly or indirectly connected) on a common base plate 52. If desired, a motor could be provided for each pump, for direct connection therewith. As can be seen in FIGS. 7 and 10, for example, the pumps 66 are indirectly connected to the motor through intervening elements, including a series of interengaging chain loops 96. The pumps are preferably arranged in two spaced-apart serial arrays, one on each side of motor 68. Except for the pumps located at the ends of the serial arrays, pumps 66 are connected to pairs of chain sprockets so as to form a drive system in each serial array, driven from a single point in the array (preferably at the drive shafts coupled to the end pumps shown at the bottom of FIG. 7). Connecting members 98 connect the sprocket drive shafts to a transmission member, preferably a gear box 100. A pulse encoder 102 informs the control circuitry of the rotation of the pumps 66.

Referring to FIG. 10, the pumps 66 are mounted by sleeves 106 to mounting walls 110 which are preferably C-shaped in cross section. As can be seen in FIG. 10, the pumps 66 are cantilevered from mounting walls 110. Referring additionally to FIGS. 11 and 12, the pumps 66 include an inlet port 112 and an outlet port 114. The pumps 66 have an outer housing 120 with a first end 122 remote from sleeves 106, and a second end 124 which includes a mounting hub 126 with an annular recess 128. The mounting hub 126 fits within a first end 130 of mounting sleeve 106 and is held in place by a set screw (not shown), the inner tip of which is received in recess 128. Sleeves 106 include a second end 134 which is stepped, having a large diameter outer surface portion 136, a smaller diameter externally threaded surface portion 138 and a stepped wall 140 therebetween. In the preferred embodiment,

the stepped wall 140 comprises a reference surface for locating the pump sleeve on mounting walls 110.

FIGURE 9 shows mounting wall 110 prior to installation of the pump sleeves therein. In the preferred embodiment, weld nuts 144 are welded to an inner surface of mounting channel 110, in registry with apertures 146 formed in the mounting wall. The pump sleeves are threadingly engaged with the mounting wall, as if they were a bolt. The pump mounting head is then installed in the open free end of the mounting sleeve and secured with the aforementioned set screw. As can be seen in FIGS. 11 and 12, the pump shaft 150 extends into the inner bore 152 of the mounting sleeve. Couplings 154 (see FIG. 10) join the pump shaft 150 with the drive shaft 156 of sprockets 160, thus completing connection to the drive motor. As can be seen in FIG. 11, for example, an inspection port 164 facilitates assembly of the coupling 154.

As can be seen in the side elevational view of FIG. 8, the pump assembly 50 is of a low profile design, with centerlines of the pumps and of the motor lying in closely spaced horizontal planes. The pump arrays are horizontally oriented, as is the drive shaft and outer body of motor 68.

The construction of pump 66, of the mounting sleeve 106 and of the arrangement of the weld nuts 144 and mounting channels 110 cooperate to provide heretofore unattainable reduction in pump wear. The pump and pump mounting arrangements described herein are believed to more accurately align the rotational axes of the pump and associated mounting systems, when mated to form the pump assemblies 15. The reduced wear and improved alignment, however, need not be employed with gang-driven pumps, as shown in the pump assembly 50, but could be employed where a single pump is driven by a power source, such as an electric motor.

The pump 66 shown in FIG. 14 includes the aforementioned outer housing 120 having a first end 122, a second end 124 and an internal bore 170. As can be seen in FIG. 14, the drive shaft 150 extends beyond the mounting hub 126. Shaft 150 has an enlarged diameter portion 174 supported by sleeve bearings mounted within internal bore 170. The sleeve bearings 176 are located immediately adjacent a rotor 178 which is formed at the interior end of shaft 150. The rotor 178 appears L-shaped in cross section since it is not symmetric about a midplane passing through the center of the rotational axis. In the preferred embodiment, the rotor 178 has nine drive teeth 180 (visible in FIG. 14 as one leg of the "L"). An idler gear 182 is mounted for rotation to a head member 184 by a pin 186. The idler gear 182 is also preferably not symmetrical when viewed in cross section. In FIG. 14, the idler gear includes gear teeth 190. In FIG. 14, a gear tooth cut by the cross section appears above pin 186, while a valley between adjacent gear teeth is located below pin 186. Head 184 is secured to housing 120 by a series of bolts 194. Inlet and outlet passageways are formed in housing 120, on diametrically opposed side portions of idler gear 182. An inlet passageway 196 is shown in phantom in FIG. 14.

The pump 66 includes a second sleeve bearing 200 adjacent the exposed free end of the pump shaft 150. Head 184 maintains fluid-tight enclosure of internal bore 170 at the first end of pump 66. In order to maintain a fluid-tight closure at the second end of the pump, a pair of seals are employed. FIG. 14 shows seals 204, 206 which have engaging mating faces. Typically, one seal rotates with drive shaft 150, while the other seal remains stationary, although other arrangements are also possible. For example, both seals could be allowed to rotate with drive shaft 150

with appropriate provision of rotational mounting for the seal located adjacent bearing 200. Seal 206 is mounted in a holder 210 which preferably engages the out surface of the rotor shaft. A spring 212 is
5 positioned between bushing 176 and holder 210, so as to bias the seals 204, 206 together, in mating engagement. A washer 214 is located between spring 212 and bushing 176 to reduce wear.

Initially, there is little or no "end play"
10 in the drive shaft 150. However, with prolonged use, some end play may develop, and spring 212 presses the rotor head into engagement with the idler gear, and also presses the free ends of rotor teeth 180 into engagement with the mating face of head 122. In the
15 preferred embodiment, the idler gear 182 and mounting pin 186 are of hardened construction, preferably hardened cast iron, and most preferably ceramic. The rotor and especially the teeth 180 are also of hardened construction, preferably hardened cast iron. The head
20 122 is also of hardened construction, preferably hardened cast iron of greater hardness than the rotor, so as to provide continuous adjustments during prolonged pump use (with attendant wear on the rotor 178 and head 122), so as to maintain a constant pump
25 output over the useful life of the pump.

In the preferred embodiment, the idler gear 182 is made of ceramic material and has a hardness greater than that of the head and rotor. The head member is fabricated so as to have an intermediate
30 hardness of the three parts, that is, a lesser hardness than idler gear 182 but a greater hardness than the rotor 178. After prolonged use, the free ends of rotor 180 will wear, so as to have a reduced length in the axial direction. The idler gear 182 sees an increased
35 pressure applied by rotor 178 and, being harder than the rotor, bores into the face 222 of the rotor,

thereby effectively extending the length of rotor teeth 180 in the axial direction, as well as the slots between adjacent rotor teeth, thereby preserving the volume pumped for a given amount of rotation. Because
5 the head member 122 is harder than the rotor, a compensating wear develops at the rotor face 222 rather than at the head member 122.

Referring now to FIGS. 15-22, the valve tray subassembly includes a mounting plate 230 in the form
10 of a tray having a horizontal plate-like portion 232 and a downturned rear wall 234. The dispense head assembly 44 is mounted at the forward end of the tray, and is coupled to the dispense valves 60 by a plurality of tubing segments 240. Referring additionally to FIG.
15 21, the dispense head assembly 44 includes a nozzle portion 244 downwardly depending from a body portion 246 which is preferably formed from a plastic block, machined to form flow channels, one for each conduit 240 extending to the nozzle 244.

20 In the preferred embodiment, three flow channels emerge from each sidewall and from the rear wall of the body portion 246. The tubing segments are arranged side-by-side and are trained to generally follow the horizontal plate portion 232 of tray 230.
25 As can be seen in FIG. 16, the tubing segments "fan out" from the sidewalls and rear wall of the body member 246. The tubing segments are connected to dispense ports 250 of the valve 60. In the preferred embodiment, dispense valves 60 are mounted directly to
30 rear wall 234 of tray 230.

However, as indicated in FIG. 16, the dispense valves 60 could be mounted to an intermediate plate 254 which is in turn mounted to rear wall 234. The mounting plate 254 has elongated mounting holes
35 (not shown) to receive threaded fasteners (not shown) received in rear wall 234. Mounting plate 254 can be

5 moved small amounts in a vertical direction, so as to control the amount of slope, if any, to the tubing segments 240. In the alternative embodiment shown in FIG. 16, the mounting plate 254 can be repositioned so as to introduce or alternatively eliminate a small downward slope in the tubing segments, as desired. The tubing segments should be of flexible construction to allow these adjustments.

10 Referring additionally to FIG. 4, the pump outputs are connected through conduits 260 to the inlet ports of dispense valves 60. Conduits 262 couple the outlet ports 264 to canisters 58, with conduits coupling the canisters to the pump inlet ports. In the preferred embodiment, material to be dispensed is
15 stored in canisters 56, 58 and is pumped through conduits 260 to dispense valves 60. The dispense valves 60 are configured such that the material circulates through the dispense valves, exiting through outlet ports 264 to return to canisters 56, 58 via
20 conduit 262. When a dispensing cycle is initiated, control circuitry 72 initiates commands to dispense valves 60 through conductors 270, and flow is diverted through outlet ports 250, for passage through tubing segments 240 and dispense head 268 to dispense nozzle
25 244. The recirculation prevents settling in the various conduit lines, and also prevents settling in the canisters, augmenting the stirrers 280, driven by electric motor 282 (see FIG. 4).

A lamp 290 is mounted to printed circuit
30 board 292 which is secured to the upper surface of dispense head 246. The lamp 290 is received in a passageway 294 formed at the center of the dispense head 246 and the dispense nozzle 244, so that illumination from lamp 290 indicates the desired
35 positioning of a container to receive dispense materials. Referring to FIG. 21, stainless steel

nozzle extensions 298 are positioned at the bottom end of dispense nozzle 244, the nozzle extensions projecting small amounts beyond the bottom surface 300 of the dispense nozzle. The flow passageways in the
5 dispense nozzle 244 and dispense head 246 are indicated in phantom in FIG. 21.

The drawings and the foregoing descriptions are not intended to represent the only forms of the invention in regard to the details of its construction
10 and manner of operation. Changes in form and in the proportion of parts, as well as the substitution of equivalents, are contemplated as circumstances may suggest or render expedient; and although specific terms have been employed, they are intended in a
15 generic and descriptive sense only and not for the purposes of limitation, the scope of the invention being delineated by the following claims.

WHAT IS CLAIMED IS:

1. Dispensing apparatus, comprising:
 - a frame;
 - a drive assembly including a base plate, a drive motor and a plurality of pumps mounted on the
 - 5 base plate;
 - a first plurality of canisters having top and bottom ends and preselected shorter length, coupled to first ones of the pumps;
 - a second plurality of canisters, of
 - 10 preselected longer length and having top and bottom ends and coupled to second ones of the pumps;
 - the bottom ends of the first and the second plurality of canisters arranged generally coplanar, immediately above the drive assembly;
 - 15 a lower shelf mounted to the frame above the first plurality of canisters and hinged to allow access to the first plurality of canisters;
 - a dispense head coupled to the pumps and located above the canisters so as to overhang the lower
 - 20 shelf;
 - an access door above the second plurality of canisters and hinged to allow access to the second plurality of canisters;
 - an upper shelf extending from the access door
 - 25 so as to be interposed between the lower shelf and the dispense head.
2. The dispense apparatus according to claim 1 wherein the valve tray assembly includes a tray having a forward end and a rearward end, with the dispense head mounted at the forward end of the tray.

3. The dispense apparatus according to claim 1 further comprising a plurality of dispense valves coupled between the pumps and the dispense head.

4. The dispense apparatus according to claim 1 wherein the dispense valves are arranged in a serial array and mounted at the rearward end of the tray, and the dispense apparatus further comprises a plurality of
5 tubing segments joining the dispense head to the dispense valves, the tubing segments aligned side-by-side in a common generally horizontal plane extending generally parallel to the tray.

5. The dispense apparatus according to claim 1 wherein the dispense valves have inlet and outlet ports for coupling to the pump means, and a dispense port for coupling to said either tubing segments, said
5 dispense valves being selectively operable to direct material from the inlet port to the dispense port or to return material to the canister.

6. The dispense apparatus according to claim 1 further comprising conduit means coupling the dispense valves and pumps to form a recirculation loop therebetween and to provide material to the dispense
5 valves for selective delivery to the dispense head.

7. The dispense apparatus according to claim 1 wherein the pumps are arranged in two spaced serial arrays with at least one electric motor disposed between the two spaced serial arrays and coupled to the
5 pumps in driving engagement therewith.

8. The dispense apparatus according to claim 7 wherein each serial array comprises at least one drive chain coupling the pumps to the motor.

9. The dispense apparatus according to claim 8 further comprising a pair of mounting walls, with the motor located between the mounting walls, and with mounting walls located between the motor and the pumps.

10. A pump assembly for use in a fluid dispenser, comprising:
a base plate;
a pair of mounting walls upstanding from the
5 base plate;

a plurality of pumps arranged in two spaced serial arrays, each array mounted to a respective mounting wall; and

at least one electric motor disposed between
10 the two spaced serial arrays and coupled to the pumps in driving engagement therewith.

11. The pump assembly according to claim 10 wherein the motor is located between the mounting walls, with the mounting walls located between the motor and the pumps.

12. The pump assembly according to claim 10 further comprising a plurality of attaching means having first ends secured to the mounting walls and second ends to receive the pumps.

13. The pump assembly according to claim 10 wherein the attaching means comprises hollow sleeves having first ends extending through the mounting walls and second ends engaging respective ones of said pumps.

14. The pump assembly according to claim 13 wherein the first ends of the sleeves are threaded, and the pump assembly further comprises nut fasteners for

5 mating engagement with the sleeve first ends to engage the mounting walls.

15. The pump assembly according to claim 14 wherein the nut fasteners are secured to the walls.

16. The pump assembly according to claim 10 further comprising drive shafts extending through the mounting walls and into the first ends of the sleeve,s and coupling means for coupling the drive shafts to
5 respective pumps.

17. The dispense apparatus according to claim 16 wherein each serial array comprises at least one drive chain coupling the pumps to the motor.

18. The pump assembly according to claim 16 wherein the drive shafts are secured to respective sprockets.

19. The pump assembly according to claim 10 further comprising pairs of bearing supports within the sleeves for rotationally supporting the drive shafts, the bearing supports located on opposite sides of the
5 mounting walls.

20. In a dispensing apparatus, comprising:
a pump;
a source of material to be dispensed, the source coupled to the pump;
5 a plurality of valves coupled to a respective pump;
a dispense head coupled to the valves;
the improvement wherein the pump comprises:

10 a housing having first and second ends and
defining an internal bore, an inlet passageway, and an
outlet passageway;

15 a drive member within the internal bore
including a rotor having rotor teeth and a drive shaft
extending from the rotor toward the first end of the
housing;

a head member at the second end of the
housing including a curved wall between the inlet
passageway and the outlet passageway and extending
toward the rotor;

20 an idler gear having gear teeth;

mounting means for rotationally mounting the
idler gear to the head member so that the rotor teeth
engage the gear teeth and so that the gear teeth pass
between the inlet passageway and the outlet

25 passageway, adjacent the curved wall;

the head member and idler gear having a
preselected hardness greater than that of the rotor.

21. The dispense apparatus according to claim
20 wherein the idler gear is made of ceramic material
and is rotatably mounted to the pump head member by a
pin of ceramic material.

22. The dispense apparatus according to claim
21 wherein the pump head member is made of hardened
cast iron.

23. The dispense apparatus according to claim
21 further comprising a bearing support surrounding the
rotor.

24. The dispense apparatus according to claim
23 further comprising an other bearing support adjacent

the first end of the housing, surrounding the drive shaft.

25. The dispense apparatus according to claim 24 further comprising a pair of mating seals adjacent the other bearing, and a bias means for biasing the seals together in sealing engagement with one another.

26. The dispense apparatus according to claim 21 wherein the bias means comprises a spring element disposed between the seals and the rotor so as to press the seals together in sealing engagement with one another and to also press the rotor into engagement with the head member.

27. The dispense apparatus according to claim 21 wherein at least one of the seals is made of ceramic material.

28. In a dispensing apparatus, including:
a pump;
a canister for supply of material to be dispensed, coupled to the pump;
5 a plurality of valves coupled to a respective pump;
a dispense head coupled to the valves;
the improvement comprising:
the pump having a mounting hub extending
10 along an axis and a drive shaft extending along the axis beyond the mounting hub;
a mounting wall defining a mounting aperture;
a tubular sleeve mounting the pump to the mounting wall, the sleeve having opposed first and
15 second ends, the first end receiving the mounting hub and the drive shaft and the second end having an outer surface with a first surface portion of predetermined

diameter, a second surface portion of reduced diameter
and a radially extending step therebetween for engaging
20 the wall so as to align the axis at a predefined angle
to the mounting wall; and

securement means for securing the sleeve
second end to the wall.

29. The improvement according to claim 28
wherein the first end of the sleeve is threaded, the
securement means comprising a nut fastener for mating
engagement with the sleeve first end to engage the
5 mounting wall.

30. The improvement according to claim 29
wherein the nut fastener is permanently secured to the
wall.

31. The improvement according to claim 28
further comprising a drive shaft extending through the
mounting wall and into the first end of the sleeve, and
coupling means for coupling the drive shaft to the
5 pump.

32. The improvement according to claim 31
wherein each serial array comprises at least one drive
chain coupling the pumps to the motor.

33. The improvement according to claim 31
wherein the drive shaft is secured to a sprocket.

34. The improvement according to claim 28
further comprising a pair of bearing supports within
the sleeve for rotationally supporting the drive shaft,
the bearing supports located on opposite sides of the
5 mounting wall.

35. The improvement according to claim 28 further comprising:

a frame for supporting the mounting wall;
a motor mounted on the frame for preselected
5 alignment with the mounting wall; and
coupling means for coupling the motor to the pump in driving engagement therewith the sleeve maintaining alignment between the motor and the pump drive shaft.

36. A valve assembly including:

a tray having a forward end and a rearward end;

a dispense head mounted at the forward end of
5 the tray, the dispense head having a body with top and bottom walls and at least one sidewall therebetween, a multichannel dispense nozzle downwardly extending from the body and the body defining a plurality of flow channels extending from the dispense nozzle to the at
10 least one sidewall, the flow channels arranged side-by-side in a common, generally horizontally extending plane;

a plurality of dispense valves arranged in a serial array and mounted at the rearward end of the
15 tray; and

a plurality of tubing segments joining the dispense head to the dispense valves, the tubing segments aligned side-by-side in a common plane extending generally parallel to the tray.

37. The valve assembly according to claim 36 wherein the dispense valves are secured to the valve tray which is in turn adjustably secured to the tray.

38. The valve assembly according to claim 36 wherein the dispense nozzle has outlet openings

arranged in a circle with a lamp at the center of the circle.

39. The valve assembly according to claim 36 wherein the dispense valves have inlet and outlet ports and a dispense port for coupling to said tubing segments, said dispense valves being selectively
5 operable to either direct material from the inlet port to the dispense port or to return material to the canister.

40. The valve assembly according to claim 36 wherein the dispense valves have inlet and outlet ports for coupling to a closed loop circulation system and a dispense port for coupling to said tubing segments,
5 said dispense valves being selectively operable to direct incoming flow through the dispense valve to the outlet port during an idle condition and for diverting incoming flow to the dispense port during a dispense condition.

41. Dispensing Apparatus, comprising:

a frame;

a drive assembly including a base plate, a plurality of pumps arranged in two spaced serial arrays
5 mounted on the base plate and at least one electric motor disposed between the two spaced serial arrays and coupled to the pumps in driving engagement therewith;

a first plurality of canisters, of preselected shorter length and having top and bottom
10 ends;

a second plurality of canisters, of preselected longer length and having top and bottom ends;

- the first and the second plurality of
- 15 canisters having generally coterminous bottom ends located immediately above the drive assembly;
- a dispense head having a body with top and bottom walls and at least one sidewall therebetween, a multichannel dispense nozzle downwardly extending from
- 20 the body and the body defining a plurality of flow channels extending from the dispense nozzle to the at least one sidewall, the flow channels arranged side-by-side in a common, generally horizontally extending plane;
- 25 a valve tray assembly including a tray having a forward end and a rearward end, a dispense head mounted at the forward end of the tray, a plurality of dispense valves arranged in a serial array and mounted at the rearward end of the tray, and a plurality of
- 30 tubing segments joining the dispense head to the dispense valves, the tubing segments aligned side-by-side in a common generally horizontal plane extending generally parallel to the tray;
- mounting means for mounting the valve tray
- 35 assembly to the frame so that the dispense valves are located above at least one of the arrays of pumps; and
- conduit means coupling the dispense valves and pumps to form a recirculation loop therebetween and to provide material to the dispense valves for
- 40 selective delivery to the dispense head; and
- the dispense valves having inlet and outlet ports for coupling to said conduit means, and a dispense port for coupling to said tubing segments, said dispense valves being selectively operable to
- 45 direct material from the inlet port to the dispense port.

BOX I. OBSERVATIONS WHERE CLAIMS WERE FOUND UNSEARCHABLE

2. Where no meaningful search could be carried out, specifically:

It is not clear from the specification how the pump is constructed or operates. Specifically, in the specification on pages 13-15 and in Fig.14 the construction of the pump (66) is described. The specification teaches, and the examiner understands that the pump includes:

An L-shaped rotor (178) having preferably nine drive teeth (180) and an idler gear (182) having gear teeth (190), a spring (212) which presses the rotor head into engagement with the idler gear. The idler gear and the rotor being made of materials of different hardness which promote a constant pump output over the useful life of the pump as the parts wear.

It is not clear from the specification and drawings taken together how specifically these parts interrelate to form an operational pump. It is not clear where the pump chamber is located, where the inlet and outlet enter and exit the pump chamber, how material is motivated through the pump chamber, and what relation the rotor and idler gear play in the operation of the pump in the pumping operation. In claims 20-27 the specifics of the pump is claimed but the operation of the pump is not understood therefore the claims are not understood

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I Claims 1-9, 20-27, 28-35 and 41, drawn to a dispensing apparatus.

Group II Claims 10-19, drawn to a plural pump assembly.

Group III Claims 36-40, drawn to a plural valve assembly.

The inventions listed as Groups I, II, and III do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: because the special technical features of Groups II and III have been omitted from Group I. And similarly, the special technical features of Groups II and III have been omitted from each other.
